

1 Indication

Distal fibula fractures in geriatric patients.

2 Storage & Access

Positioning in supine position on normal table with free BV access.

Reduction by longitudinal traction using ligamentotaxis.

Skin incision (approx. 1.5 - 2.0 mm) from the outer tip of the ankle to the distal side.

Attention!

Risk of injury to the peroneal tendons if the incision is too deep!

3 Entry point

Determine the optimal entry point for the intramedullary guide wire using the image converter.

4 Medullary space opening

Set the drill guide system and ream the cortex using a Ø 2.5 mm drill. Image converter control during axial internal rotation of the lower leg.

5 Positioning the guide wire

Insertion of the guide wire using the drill guide system.

Removing the first drill sleeve insert.

6 Drilling the core diameter

Ream the proximal narrow medullary canal to the core diameter of the screw using a cannulated drill Ø 3.5 mm through the tissue protection sleeve and over the guide wire. At the same time, we recommend using the drill under X-ray control to determine the appropriate screw diameter.

Tip!

Careful manual compression allows for better medullary cavity drilling.

7 Insertion of the screw

The screw is inserted through the tissue protection sleeve so as not to injure the skin surface by the sharp thread flanks. If necessary, manual compression of the fracture region.

Tip!

With the help of the inspection hole in the tissue protection sleeve, a more precise determination of the position of the screw is possible.

8 Position control

Before removing the guide wire, a check is made in both planes.

The screw should at least be flush with the bone surface. If necessary, this can also be screwed in deeper.
